Summary

Human longevity is characterized by a remarkable lack of confirmed genetic associations. Here, we report on the identification of a novel locus for longevity in the RAD50/IL13 region on chromosome 5q31.1 using a combined European sample of 3208 long-lived individuals (LLI) and 8919 younger controls. First, we performed a large-scale association study on 1458 German LLI (mean age 99.0 years) and 6368 controls (mean age 57.2 years) by targeting known immune-associated loci covered by the Immunochip. The analysis of 142 136 autosomal single nucleotide polymorphisms (SNPs) revealed an Immunochip-wide significant signal (PImmunochip = 7.01 × 10^{-7}) for the SNP rs27065650 in the TOMM40/APOE region, which has been previously described in the context of human longevity. To identify novel susceptibility loci, we selected 15 markers with PImmunochip < 5 × 10^{-8} for replication in two samples from France (1257 LLI, mean age 102.4 years; 1811 controls, mean age 49.1 years) and Denmark (493 LLI, mean age 96.2 years; 740 controls, mean age 63.1 years). The association at SNP rs2706372 replicated in the French study collection and showed a similar trend in the Danish participants and was also significant in a meta-analysis of the combined French and Danish data after adjusting for multiple testing. In a meta-analysis of all three samples, rs2706372 reached a P-value of PImmunochip-Repl = 5.42 × 10^{-7} (OR = 1.20; 95% CI = 1.12–1.28).

SNP rs2706372 is located in the extended RAD50/IL13 region. RAD50 seems a plausible longevity candidate due to its involvement in DNA repair and inflammation. Further studies are needed to identify the functional variant(s) that predispose(s) to a long and healthy life.

Key words: 5q31.1; genetic association; human longevity; IL13; Immunochip; RAD50.

Despite more than 20 years of research into the genetic basis of human longevity, only alleles in the APOE and FOXO3 genes have repeatedly been shown to be associated with survival to very advanced ages (Schächter et al., 1994; Willcox et al., 2008; Flachsbart et al., 2009; Soerensen et al., 2010; Deelen et al., 2013). APOE and FOXO3 were initially detected in candidate-driven case–control investigations, but APOE has since then been confirmed in a number of genome-wide association studies (GWAS). In addition, a single nucleotide polymorphism (SNP) on chromosome 5q33.3 was recently identified in a GWAS meta-analysis on long-lived individuals (LLI) aged ≥ 90 years (Deelen et al., 2014). Besides the detection of APOE and the 5q33.3 locus, longevity GWAS have been relatively unsuccessful and have failed to reveal novel associations with genome-wide significance or sufficient reproducibility (Deelen et al., 2011, 2014; Nebel et al., 2011). Here, we performed a large-scale candidate gene study by targeting established immune-associated loci present on the Immunochip (Trynka et al., 2011). The Immunochip was designed to perform fine-mapping of GWAS loci of major immune-mediated diseases using data from the...
1000 Genomes Project and other sequencing initiatives. The application of the array in this study is based on the hypothesis that a well-functioning immune system and efficient anti-inflammatory networks are potent longevity-assurance mechanisms (Franceschi et al., 2007). We employed the Immunochip to screen 1458 German LLI and 6368 younger controls in a discovery phase (panel A in Table S1) for novel longevity loci followed by replication in 1750 LLI and 2551 younger controls from France and Denmark (panel B in Table S1).

After applying conservative and established quality filters to the German longevity sample, 142 136 autosomal SNPs were available for association analysis (see Appendix S1). We used a predefined threshold of \( P = 6.15 \times 10^{-7} \) to define statistical significance for the Immunochip-wide analysis, based on the Bonferroni correction for the number of linkage disequilibrium (LD)-independent markers on the Immunochip (see Appendix S1). The comparison of the case-control frequencies yielded an Immunochip-wide significant association signal for the SNP rs2075650 in the TOMM40/APOE region (\( P_{\text{Immunochip}} = 7.01 \times 10^{-9} \), OR = 0.69; 95% CI = 0.60–0.78; Table 1, Figs S1 and S2a). This SNP is in moderate LD (\( r^2 = 0.52 \)) with SNP rs429358 that defines the well-established APOE e4 allele (Deelen et al., 2011), and hence, rs2075650 was not considered for replication. With regard to the FOXO3 and the S333.3 loci, the Immunochip is uninformative due to poor coverage (Fig. S2b,c). Eighty-four other SNPs showed \( P_{\text{Immunochip}} < 5 \times 10^{-8} \) in the discovery Immunochip analysis (Table S2). Of these, we selected 15 markers for replication, each one representing the best SNP for a specific associated region defined by the clumping procedure (see Appendix S1, Table S3). The replication analysis was performed in two longevity samples from France and Denmark (France: 1257 LLI and 1811 controls; Denmark: 493 LLI and 740 controls; panel B in Table S1). The signal at SNP rs2076372, located in a region encompassing RAD50 (Fig. 1), replicated in the French sample (\( P_{\text{Repl-France}} = 2.69 \times 10^{-7} \); OR = 1.21; 95% CI = 1.07–1.38; \( P_{\text{Repl-Denmark; adj}} = 0.04 \) (corrected for 15 tests)) (Table S4). In the smaller Danish sample, the allelic effect of rs2076372 reached a \( P \)-value of 4.95 \( \times 10^{-7} \) (OR Denmark: 1.21; 95% CI = 1.09–1.34; \( P_{\text{Repl-Denmark; adj}} = 0.0074 \) (corrected for 15 tests)). In the combined French-Danish replication sample, meta-analysis association analysis yielded a \( P \)-value of 4.95 \( \times 10^{-7} \) (OR = 1.21; 95% CI = 1.09–1.34; \( P_{\text{Repl-France-Denmark; adj}} = 0.0074 \) (corrected for 15 tests)). In a meta-analysis of the German discovery and French-Danish replication samples, rs2076372 reached a \( P \)-value of 5.42 \( \times 10^{-7} \) (Table 1). Estimates of odds ratios for rs2076372 were consistent across all three studies (\( OR_{\text{Germany}} = 1.19 \); \( OR_{\text{Denmark}} = 1.19 \); \( OR_{\text{France}} = 1.21 \); statistical metric of heterogeneity \( I^2 = 0.0 \)), supporting the validity of the association finding.

Our targeted immune gene approach on a combined European sample of 3208 LLI and 8919 controls resulted in the identification of a novel association for longevity in the RAD50I113 region on chromosome 19q13.32. The lead SNP rs2076372 is located in the intrinsic region of the RAD50 gene and is in strong LD with other associated SNPs close to IL13 and IL5. The actual association signal extends even further to include additional genes (Fig. 1). At this point, this observation renders it difficult to assess which gene is actually affected by the association, although RAD50 is a plausible candidate. The protein encoded by RAD50 is highly similar to Saccharomyces cerevisiae Rad50 which is involved in repairing DNA double-strand breaks. Similarly, the human RAD50 is integrated in a functional DNA-binding complex (Kinoshita et al., 2015) that is important for recombination, repair, and genomic stability (Trujillo et al., 1998). Hence, it is conceivable that variation in RAD50 could positively influence longevity by increasing DNA stability.

Table 1 Immunochip locus associated with human longevity, S333.1. (RAD50I113) is a newly associated locus.

the expression of the neighboring cytokine genes (Roth et al., 2014). Second, the RAD50 gene harbors at its 3’ end an evolutionarily highly conserved locus control region (LCR; Lee et al., 2003; Li et al., 2010) that regulates the expression of the neighboring cytokine genes IL-4, IL-13, and IL-5 (Fig. 1) in Th2 cells (Kelly & Locksley, 2000). Variants in the LCR were found to be associated with asthma (Li et al., 2010). Taken together, these findings indicate that the RAD50 locus may very well contribute to longevity via its role in inflammation and immunity. Nevertheless, it is still possible that the RAD50 signal is a result of its LD with other markers within the observed association boundaries. Multiple SNPs in the extended RAD50/IL13 region were previously identified as susceptibility factors for various chronic inflammatory diseases such as Crohn’s disease, psoriasis, asthma, and atopic dermatitis (Rioux et al., 2000; Li et al., 2008, 2010; Paternoster et al., 2011). Further studies are therefore needed to identify the functional variant(s) and the underlying molecular mechanisms that predispose(s) to a long and healthy life.
