BACKGROUND
SP-D is a collectin widely distributed on mucosal surfaces of the body including the gastrointestinal tract (1). It is part of the innate immune system and mediates control of pro-inflammatory mechanisms.

Genetic variations of SP-D have recently been associated to inflammatory bowel disease (IBD) in a Japanese population and showed association to ulcerative colitis (UC) (2). In contrast, an American case-control analysis revealed a significant association between a specific SP-D genetic variant and susceptibility to Crohn’s disease (CD), but not to UC (3).

Together these two studies suggest that SP-D is involved in IBD and warrant in vivo studies of the related pathophysiological mechanisms.

AIM
We aimed to investigate the expression of SP-D in IBD patients and compared it to the intestinal inflammatory activity, and we compared the inflammatory response between Spdpd+ (WT) and Spdpd− (KO) mice in a dextran sodium sulfate (DSS) model of colitis.

We hypothesized that SP-D dampens intestinal inflammation by reducing innate inflammatory signaling and facilitate clearance of apoptotic cells.

METHODS
Surgical specimens from IBD patients (n=27) including Crohn’s disease (CD) (n=9) and ulcerative colitis (UC) (n=18) were immunohistochemically stained for SP-D. The tissue specimens was scored for SP-D expression and inflammatory activity.

Colitis was induced in WT and KO littermates by supplementing the ad libitum water with DSS.

Day 0: Start of treatment with DSS
Day 10: Mice are terminated after receiving water for 3 days
Day 7: Mice receiving 1.5% DSS are terminated
Colon tissue were stained with hematoxylin & eosin to estimate the histological damage, and immunohistochemical staining’s were used to analyze levels of apoptosis, necrosis and inflammatory infiltration.

Colon tissue samples were analyzed for inflammatory markers (TNF-α, IL-6, INF-γ and CCL-2) by ELISA analysis.

RESULTS
- We found a significant correlation between the expression of intestinal SP-D and inflammatory activity in IBD patients (Fig. 1).
- Mice treated with DSS did experience a notable weight loss and increased disease activity index (DAI) score (Fig. 2), but there were no difference between WT and KO.
- ELISA analysis showed a significant difference in the levels of TNF-α between WT and KO in the restitution phase and qRT-PCR did show a tendential upregulation of Spdpd in WT mice treated with DSS (Fig. 3, A-B). There were no difference in histologic damage or colon length between WT and KO (Fig. 3, C-D).

CONCLUSION
- Limited anti-inflammatory effects of SP-D in DSS-induced inflammation in mice.
- Positive correlation between inflammatory activity and immunoscore for SP-D observed in surgical specimens from IBD patients.
- SP-D is upregulated in clinical disease.
