**Objectives:** Amino acids and analogues thereof play an important role in the growth of many tumor cells. The clinical value of radiolabelled amino acids such as methionine, fluoroethyltyrosine and fluorodopa has been confirmed in a plethora of studies [1]. We sought to prepare, formulate and apply a metabolically stable analogue of the amino acid alanine for system A transport, namely $[N$-methyl-$^{11}\text{C}]\alpha$-methylamino-isobutyric acid, $[^{11}\text{C}]{\text{MeAIB}}$ [2].

**Methods:** The labelling precursor, $[^{11}\text{C}]\text{MeOTf}$, was prepared on a Tracerlab FXc Pro by standard in-line gas-phase conversions from $[^{11}\text{C}]\text{CO}_2$. The $[^{11}\text{C}]\text{MeOTf}$ was bubbled through a cooled solution of precursor in CH$_3$OH, CH$_3$CN and pentamethylpiperidine at 5 °C. The solution was warmed to 60 °C for 1 min, where 2 M NaOH was added. The heating was continued for 3 min. Shortly after, the mixture was automatically injected onto a semipreparative HPLC column via a 2 mL loop.

![Figure 1: Synthesis of $[^{11}\text{C}]\text{MeAIB}$](image)

The HPLC purification was performed in aqueous, buffered CH$_3$CN. Hence, the fraction containing the product was separated and diluted with 0.2 M H$_2$PO$_4$. This solution was loaded onto a Strata-X-C column, which was washed with sterile 0.1 M HCl and isotonic, sterile saline. The product was eluted with sterile 10 mL 2% Na$_2$HPO$_4$ through a sterile filter and into a sterile vial. Male athymic nude rats (HsdHan™:RNU-FOXn1™) were intracranially implanted in the right hemisphere with 300,000 low passage human glioblastoma single cells suspended in HBSS (Invitrogen) with 0.9% glucose (SAD 500 mg/mL). Four weeks post-implantation, rats with infiltrating glioblastomas were anesthetized and PET/CT scanned using a Siemens Inveon system after tail vein injection of $[^{11}\text{C}]\text{MeAIB}$, $[^{11}\text{C}]\text{methionine}$ or $[^{18}\text{F}]\text{FDG}$. Immediately after injection a dynamic acquisition was commenced.

**Results:** The full synthesis of $[^{11}\text{C}]\text{MeAIB}$ including purification by prep. HPLC, solvent exchange by solid phase extraction and formulation takes about 35 min. delivering 2-5 GBq in 10 mL sterile phosphate-buffer. In all cases pH was maintained between 6.3-6.8 and the content of CH$_3$CN was below 350 ppm. We have produced and more than 40 productions in the described manner. After administration to orthotopically implanted nude rats the glioblastoma were visualized with a tumor to background (normal brain) ratio for $[^{18}\text{F}]\text{FDG}$, $[^{11}\text{C}]\text{methionine}$ and $[^{11}\text{C}]\text{MeAIB}$ of 1.5, 2.3 or 8.2, respectively.

**Conclusions:** We have demonstrated the fast and reliable production of GMP-grade $[^{11}\text{C}]\text{MeAIB}$. Also, $[^{11}\text{C}]\text{MeAIB}$ was successfully used in the imaging of human infiltrating glioblastoma in nude rats. $[^{11}\text{C}]\text{MeAIB}$ was found to have a significantly higher tumor to background ratio than $[^{11}\text{C}]\text{methionine}$ and $[^{18}\text{F}]\text{FDG}$.
