INTRODUCTION

Phycocyanobilin (PCB) is a linear tetrapyrrole chromophore covalently attached to protein subunits of phycobiliproteins, C-Phycocyanin (C-PC) and Allophycocyanin (APC), present in the light harvesting complexes of the blue-green algae *Arthrospira platensis*. PCB absorbs light in the red region of the electromagnetic spectrum, thereby exhibiting a vivid blue color. Therefore, it has great significance to the food industry due to its potential as a natural blue food color. The chemical synthesis of PCB is very complex and economically not feasible. Hence, there is a demand for the development of process to obtain PCB from phycobiliproteins. PCB is attached to the protein subunits through a cysteine residue with a thioether linkage. In this work, the kinetics of the cleavage process of PCB from protein subunits by methanolysis is investigated.

KINETIC MODEL FOR CLEAVAGE OF PCB BY METHANOLYSIS

Cleavage of PCB can be described either as two first order reactions in parallel:

$P - ν_1(PCB(I)) \rightarrow P + ν_1PCB; \quad P - ν_2(PCB(II)) \rightarrow P + ν_2PCB$

Or two first order reactions in series:

$P - ν_1(PCB(I)) - ν_2(PCB(II)) \rightarrow P - ν_1PCB(II) + ν_1PCB; \quad P - ν_2(PCB(II)) \rightarrow P + ν_2PCB$

Where PCB(I) is easily accessible and PCB(II) is less accessible for cleavage, $ν_1$ and $ν_2$ are stoichiometric coefficients of PCB(I) and PCB(II), respectively. In a batch reactor the reactions in parallel will appear as a single first order reaction and can be represented by following set of equations:

$\frac{dC_1}{dt} = -k_1 \cdot C_1; \quad \frac{dC_2}{dt} = k_1 \cdot C_1 - k_2 \cdot C_2$

Analytical solutions for set of equations above is:

$C_1(t) = C_{10} \cdot e^{-k_1 \cdot t}; \quad C_2(t) = \frac{k_1 \cdot C_{10}}{k_1 - k_2} \left( e^{-k_2 \cdot t} - e^{-k_1 \cdot t} \right) + C_{20} \cdot e^{-k_2 \cdot t}$

Where $C_{10}$ and $C_{20}$ are initial concentration of PCB(I) and PCB(II), respectively

Based on stoichiometry of reaction, the concentration of PCB can be expressed as:

$C_{PCB}(t) = ν_1 \cdot C_1(t) \cdot \left( 1 + \frac{ν_2}{ν_1} \cdot \frac{C_{20}}{C_{10}} \right) - ν_1 \cdot C_1(t) \cdot \left( 1 + \frac{ν_2}{ν_1} \cdot \frac{C_{20}}{C_{10}} \right) \cdot \frac{k_1}{k_1 - k_2} \cdot e^{-k_2 \cdot t} + ν_1 \cdot C_1(t) \cdot \frac{C_{20}}{C_{10}} \cdot e^{-k_2 \cdot t}$

EXPERIMENTAL

- Linabue (Commercial extract of *Arthrospira platensis*) boiled in 400 mL methanol for 16 h at 65 °C
- Mixture samples are taken at regular interval for HPLC analysis
- Three different initial concentration of Linabue used

RESULTS

Table 1. Model data fitted to experimental data.

<table>

Cleavage of PCB as a function of time. Fully drawn lines are calculated using the model with the parameters from Table 1.

CONCLUSION

- Kinetic model describes the experimental data adequately
- The ratio between $ν_2$ and $ν_1$ is too large compared to the prior findings where a ratio 0.2 and 0.3 is more likely if all PCB is cleaved
- Although the model explains kinetic observations well, a two step model might be an over simplification
