Possible applications of the MICREA Agents Dock, a two dimensional array of programmable electrochemically active elements, to ALife.

Device Origin and Design

The dock is a part of a larger project, MICREA Agents (McCaskill et al., 2012). The original vision of the project included two major technological components: tablets and the dock. Tablets are small (~100 x 100 x 50µm), autonomous electronic elements, comprising a form of smart, programmable, electrochemically active ‘dust’, and unlike conventional smart dust communicating via pairwise interactions rather than wireless radiation. Tablets are poured into a solution, and can interact with the surrounding solution, with each other, and with smart surfaces. A dock is such a static two dimensional array of 256 x 256 microelectrodes (see Fig. 1) beneath a fluid film and connected to a host computer, from which each of the sites may be independently controlled. One goal of MICREA Agents was to develop this technology to enable a new form of evolution through the interaction of chemistry with these new hybrid informational-electrochemical elements.

Experimental examples

Electrochemiluminescence (ECL). See Fig.2

Combinatorial galvanic deposition.

Application to ALife

The dock should be useful for novel origin of life experiments, to discover chemistry that enables the transition from nonliving to living matter. A version of the Miller-Urey experiment could be implemented, with the dock’s spatial separation and control giving far more experimental range. Redox potentials provide a specific source of energy, and specifically coated electrodes provide a programmable distribution of mineral or organic catalysts that can allow controlled investigation of complex spatially resolved chemical evolution. The dock is also able to interact in programmable ways with microparticles, including the tablets discussed previously. Such interplay between autonomous programmable mobile electrochemical elements and smart docking surfaces may allow the construction of artificially self-reproducing systems with both electronic and chemical facets, see e.g. (Tangen et al., 2015).

Further, McCaskill has proposed electronic genomes that can direct construction of artificially self-reproducing systems with both electrochemical elements and smart docking surfaces may allow the interplay between autonomous programmable mobile microparticles, including the lablets discussed previously. Such a static two dimensional array of 256 x 256 microelectrodes (see Fig. 1) beneath a fluid film and connected to a host computer, from which each of the sites may be independently controlled. One goal of MICREA Agents was to develop this technology to enable a new form of evolution through the interaction of chemistry with these new hybrid informational-electrochemical elements.

Figure 1. Left: a view of the dock close to actual size (4.6 mm square). Right: A close-up of the dock. A unit cell of the 128 x 128 array contains four electrodes (outlined by the black dotted lines), with a differential sensors and a split actuator.

Figure 2. An implementation of spatial ECL (Ru(bpy)32+ based) on the (CMO)1 dock, with each lighted site stimulated by the application of a voltage to a microelectrode (global counter electrode).

Figure 3. Portable experimental setup for the dock. The microscope camera is mounted atop of an adjustable aluminium tube, mounted onto a 3D printed scaffolding (black - with lights inside), fitted onto a 3D printed dock controller box (red). The raspberry pi host computer (running Linux) is shown on the right. Cables are removed for clarity.

Portable experimental setup

A portable experimental setup is constructed using a 3D-printed scaffolding with a USB microscope mounted on top of the dock’s controller box (red). The Raspberry PI host computer (running Linux) is shown on the right. Cables are removed for clarity.
