The potential of artificial intelligence toys
a technology-based design approach

Abstract
Artificial intelligence is moving to a next step of development and application areas. The same as electronic game, AI toy can provide a virtual, comprehensive and marketable platform, and more practical than game. It is a good step by step choice in the process of AI development.

For the definition of AI toy, it should include the features of that: entertainment and intimacy as a normal toy, naturally interactive ability as a living being, and complicate thinking as a human.

Technology-based design is fit to the development of AI toy. It can exert the advantages and explore more value for existing resources. In AI toy, it can combine AI program and common sensor to realize the function of intelligence recognition as input, and use AI program with audio, video, and mechanics to make reaction as output.

To design AI toy, designer can use question-answer method to be familiar with technology topic. And process starts with making a list of possible applications by brainstorming. After that, using technology-based criteria select out the top three. At present, the possible application areas for AI toy are entertainment, education and family. Designer need consider the possible issue in this new field and that can reference the situation in electronic game.

Keywords
Artificial intelligence, Toy, technology-based design

1. Introduction
Artificial intelligence has been developed for decades. It makes computer do more works than before. In this paper, I will give some points of view about the application of AI.

We have a dream like that computer can think, learn, create, and have emotion the same as human. [1] During the development of AI technology, scientist needs achieve the aim step by step. Combining research and development with a practical and valid market together is an optima way for development. If the market is common market, it will be a perfect combination. In the past, the most large application area for AI was electronic game. Recent years, its application area extends to real product, production procedure, software, and R&D areas. In my opinion, one of the most potential AI development and application areas for next generation is AI toy.

This paper include following four parts. At first it will analyzes that why AI toy will be the next most potential application areas for AI development. And then I will give a definition about AI toy from my vision. Following that, this paper will talk about technology-based design which is fit to AI toy development, and what kind of technology can be used in AI toy. At last, I will give some suggestion about design method and process for this kind of product. And talk about possible issues and application areas.

2. Application direction of AI technology
Many people believe Artificial intelligence technology is one of the most important directions of computer science. And it could take a dynamic change to our life in some future days. At present, AI has been widespread used in electronic game, but that just is a start. It isn't really used in extensive productive field or embedded in our daily live, because AI technology is still under developing. But the time of AI product is coming.

One of the most potential markets for future is AI toy, since it has the same advantages as electronic game and is more practical than game. It is a suitable choice for step by step in the progress to the time of human-like AI robot. John Laird said in his AAAI invited talk "artificial intelligence research and computer game have quite a bit to offer each other." [2] That shows the electronic game combined very harmonic with AI technology in common market.

The both advantage of game and toy is that they can provide a virtual, comprehensive, and marketable platform for AI research. The virtual means that before AI technology does a real job we can test it in a safe environment. And the comprehensive means this environment can simulate as real as possible for a test. The feature of marketable means it can combine development and application together. So, between technology and product, they have a mutual promotion for each other. It is an optimal combination between research and application.

3. What is AI TOY?
For more clear discussion, I need give a definition about what is AI toy from my view.

At first, it should be a toy in general meaning. “For the young, toy is an important part of the process of learning about the world and growing up. For the Adults, toy is used to form and strengthen social bonds, teach the young, remember and reinforce lessons, exercise minds and bodies, practice skills, and decorate their living spaces. Toy is more than simple amusement,
and the way they are used profoundly influence most aspects of life.” [4]

And secondly, AI toy should exert the advantage of AI technology. Rodney Brooks is the director of the MIT Artificial Intelligence Lab. He said “We propose developing the perceptual and intellectual abilities of robots so that people can interact naturally with them.” It shows that the abilities which AI should take to products always include two facts: “perceptual and intellectual”. [3] They are means interaction way and thinking way.

- About the interaction way, the special interaction skill is the fundamental feature to an AI toy. Toy use these skills to input and output information with people. There are several skills which researchers have identified are suitable for AI product. “These include the ability to recognize others, to interpret gestures and verbal expressions, and to recognize and to express emotions” (Rodney.B 1999). These skills make product communicate with people more naturally [3]

- About the think way, AI technology gives ability of learning, creation and emotion to the toy. This feature simulates the thinking way of human and makes toy can finish some work which only can be done by people in the past.

Many developers prefer to call robot toy instead of AI toy. Indeed, we have robot dream, and are striving for the aim of robot. However, in my opinion, we'd better separate different steps of the progress to make it clear. The progress start form electronic game to toy, from toy to product, from product to robot. This plan is from a total virtual environment change to the real world and to the practical human society. For distinguish future mankind-like robot, I use the term of AI toy.

4. Technology-based design

4.1 What is technology-based design

How to face the challenge of these new generation product? I propose using technology–based design method to realize the meaning of AI into our daily live. In this way, developer and designer have a stable and meaningful starting point for work. That doesn’t means the product is not for fulfilling people’s need, but the project focus on exerting the advantage and exploring more value of technology.

Technology–based design is a kind of resource-based design. Depend on different project, we can choose different starting point for a design process. Resource-based design always is compared with need-based design. For resource-based design, designers focus on what we have got already and make full use of existing resource. For need-based design, it is more like a design for dream. That means designers get an aim first, and then try to find resource to fulfill.

Technology–based design can fit such a technology time. It always likes a bridge between technology and application to improve our live. At present, more and more new technologies need to realize their meanings. Technology–based design can provide some appropriate approaches for making technology embed in daily live for common people. Scientists announce new achievements every day, but these technologies always look ahead in future and are far from real life.

AI technology is a good example for this phenomenon. Through the development process of electronic game, we can get a skim of technology-based design. Along with computer becoming faster and more powerful, the focus of PC game development moved from simple calculation to multimedia application, and moved from video and audio reappearance to human thinking simulation. All of these changes are based on the development of modern personal computer.

4.2 Technology in AI toy

The application of AI technology could be divided into two categories: intelligence recognition and thinking simulation. They are the core technology for realizing the two basic functions of AI toy—recognize information from input and generate reaction for output. Combining with diverse sensors, AI toy can use different way to get input from user, and using screen, speaker and mechanical actions to give output. That means AI toy need to use many technologies at the same time. That is a challenge and opportunity for designer to develop interesting and marketable product.

To realize the interaction feature for input, AI toy could be based on several intelligence recognition technologies listed as below: voice recognition by microphone, gesture or face character recognition by camera, fingerprint recognition by optic-sensor, and handwriting recognition by touch board. AI programs combine popularly and successful with these input devices in many products. They grant AI toy more natural abilities of recognizing and understanding. That means toys can know who is talking and playing with them, and what the meaning of these actions or words.

For output, AI can do many kinds of thinking simulation. This program can directly move from electronic game. Such as an algorithm called Neural Networks, it is an AI software system which can do a learning process. “Neural Networks can be used as a means of updating the AI system... The network can improve continuously” [5] Using this technology, toy can generate a special character to one owner. Playing longer time with it, toy can be more fit to player. Users wouldn’t feel the play is boring and easy, or understand the toy very well in a short time. For future, AI in toy will be more effective and creative. These features make AI toy more lively, natural, and attracting.

5. Design for AI toy

5.1 Design method, process and issues.

As a short summary, the technologies which could be used include these: AI program, sensors, mechanics, video and audio. The challenge to designer is that they must well understand these resources and predict possible issues.

Designer can try to answer following questions to be more familiar with the technologies in AI toy: what are their most features, what can they do, how does people use it now, what is its future, and so on. Through answer these questions, designers can find out the most possible choice. That means developer
needn’t cost time and energy to develop a totally new part for
the product, but explore more value from the mature technology
by design.

The work can start with listing possible application ways with a
brainstorming method. And then, designer gives assessment to
each way and goes some deeper research with top 3 selections.
The criteria of selection could be focus on better daily life, more
popular market, or easier produce, but the most important is the
design should exert the advantage of AI technology.

The possible issues could be whether the output reaction is
natural. The same as problems which was met during electronic
game development, an appropriate AI program need cost a lot of
time to test and improve for feeling more real and natural.
Another issue is that because AI toy is more real than game, the
influence to people should be considerate as well. Some people
would be addict to an electronic game, so it is possible that
somebody rely on an AI toy too much also. If someone used to
living with an emotional toy, and then the toy lost memory by
some error, what will happen?

5.2 Possible application area
Through the method mentioned above, we can get top 3
selections for AI toy. It could focus on entertainment, education,
and family. Designer can focus on one of these points to fit in
the market and make progress to AI research, and need consider
the possible issue also.

For entertainment purpose, it is very common to a normal toy.
People like any kinds of performance like dancing, singing,
acting and so on. But need interest, neoteric and attracting.
Machine can do some something more precisely and faster than
human. Developer can use this point to design amazing action
for a performance.

For education purpose, a toy always can be used as an
entertainment product. Toy need make reaction to user's actions
or words. It is an opportunity to influence user also. Using
this opportunity to do education is a good way for receiving
knowledge. Toy can take the scattered time to influence user in
daily life.

For family purpose, people don't like stay lonely, so we always
need accompany with others to communicate and chat. If
simulate a real people is too hard, a pet could be better in the
first stage. The living things always make people feel better and
safe, even a plant could adjust the atmosphere in the room.

6. Conclusion
The analysis above shows that now we have prepared for
the coming of robots time, and AI toy is the first step for this
journey. In such a technology time, scientists are developing
more and more technologies to improve our life. It is a great
opportunity for designers to apply these technologies into
human real life.

Intelligence recognition system and thinking simulation system
are the core technologies for AI product. Combining with
different input and output device, they build up the basic
structure of future products. This system has universal
applicability. Like personal computer, based on the basic
structure, it can use for different field by change input/output
device and software. Different AI products can use the same
principle to recognize and translate, learn and remember, think
and analysis, decide and create.

To face this situation, we can use design to combine research
and market in an appropriate way. Using right design method
and process, designers can mediate resource and need, enhance
the efficiency of work, avoid issues, and lower cost. They will
combine rational and emotional way together to solve problem
and use experience to predict possible situation.
